In this lab, you will warm up with general practice writing a simple function.

Then, you will modify the set of functions that take an object-oriented approach to drawing things used as an example in the Week 10 lectures, changing the way that boxes are represented, and then adding a new class of object.

**Practice writing a simple function.**

Write a function called `multiply_above_diagonal` that takes as its only argument a square matrix (you don’t have to check this), and returns a single number that is the product of all the elements in the matrix that are above the diagonal (ie, all those in positions where the column index is greater than the row index). Note that the product of zero factors is defined to be one.

Here is the correct output for two test cases:

```r
> Y <- matrix (1:16, nrow=4, ncol=4)
> Y

[1,]  1  5  9 13
[2,]  2  6 10 14
[3,]  3  7 11 15
[4,]  4  8 12 16
> multiply_above_diagonal(Y)
[1] 1228500
> multiply_above_diagonal(matrix(5,nrow=1,ncol=1))
[1] 1
```

**Extending the example from Week 11’s lecture.**

Next, you should extend the example of object-oriented programming in the Week 10 lecture slides, by changing the representation of box objects, and adding a new “plus” object.

The functions from the lecture slides are available at

http://www.cs.utoronto.ca/~radford/csc120/drawfuns.r

and the script that was used (in slightly different form) to produce the results in the lecture slides is at

http://www.cs.utoronto.ca/~radford/csc120/drawscript.r

As a first exercise, modify the functions for the “box” class to represent a box by a list whose elements are the same as the arguments of the `new_box` function. This may require
changing `new_box`, `draw.box`, `rescale.box`, and `translate.box`. But it should not require any change to the R code that uses boxes, in the script file.

As a second exercise, try to add a new “plus” object, which looks like a plus sign. You should write a `new_plus` function that creates an object of class "plus", given the x and y coordinates of the centre of the plus (where the two lines cross) and how far the ends of the plus extend away from the centre (the same for the horizontal and vertical lines). You should also write a `draw.plus` function to provide a `draw` method. You should then be able to try drawing plusses. Once you have this working, you can write `rescale.plus` and `translate.plus` methods for objects of this class, and try them out. You should also be able to call the `smaller` function from the lecture with a `plus` object as its argument.

Finally, you can try to implement a new generic function for these objects, called `rotate90`, that rotates an object by 90 degrees counterclockwise. You may find it convenient to define a default method for this generic function (which would need to be called `rotate90.default`). For which classes of objects could you just let the default method be used? For which will you need to write a special method for `rotate90`?
